Abstract

A resonant force sensor with semidigital frequency output based on a triple-beam resonator structure in silicon is presented. The piezoelectric excitation of the resonator operating in an antisymmetric vibration mode is realized by thin-film zinc oxide layers. An advantage of this triple-beam design is a high mechanical quality factor combined with high force sensitivity due to the antisymmetric vibration mode and the load-dependent stress concentration in the triple beam. Extensive finite-element modelling has been carried out to determine the static and dynamic behaviour and to obtain optimum sensor performance. Several resonator designs have been fabricated to study mechanical decoupling from the clamping region. Experimental characterization of the triple-beam sensor and of the zinc oxide thin-film properties has been performed.

Introduction

Resonant sensors in quartz and silicon exhibit a wide field of applications and special benefits like large gauge factors, high resolution and a semidigital frequency output [1, 2]. The resonant force sensor described in this paper is based on the principle of a resonator being excited in a specific flexural vibration mode. It changes its resonance frequency when mechanical stress is applied. One key aspect in the design of resonant sensor devices is a high mechanical quality factor, leading to high resolution and sensitivity. This can be achieved by placing the resonator in an evacuated cavity [3] and/or by using a special resonator design [4]. Disadvantages of vacuum-encapsulated resonator designs are the quite complicated fabrication technology and additionally arising packaging problems.

Bulk force sensor devices fabricated in monocrystalline quartz normally use a double-ended tuning-fork (DETF) design in order to balance the in-plane motions of the tuning-fork tines and to cancel out moments that are responsible for energy dissipation into the resonator mount [5]. Since quartz is piezoelectric, there is an easy way to excite and detect the vibration of the resonator and to operate the quartz force sensor as an electrical one-port in a feedback loop of an oscillator circuit. The fact that silicon is a non-piezoelectric material leads to the necessity to deposit ad-

ditional piezoelectric thin-film layers onto the beams to excite them. In this work we used r.f. sputtered zinc oxide (ZnO) thin films. Due to the induced bending moment of the silicon/ZnO bimorph, the flexural vibrations are out-of-plane. To achieve a cancellation of moments and shear forces at the clamped ends, in this case more than two beams are obviously necessary. A resonator comprising a triple or a quadruple beam structure is well suited for this purpose [6–8]. In this paper we report on the first realization of piezoelectrically driven resonant silicon force sensors with triple-beam design, where the centre beam has twice the width of the two outer beams and vibrates in antiphase with them.

Design and simulation

A numerical method such as finite-element analysis can be used to predict the sensor characteristics with reasonable accuracy and to analyse geometric modifications on the sensor performance. The general-purpose finite-element software program ANSYS [9] was used to predict the modal behaviour of the triple-beam resonator. The eigenfrequencies and the associated complex vibration mode shapes were determined in modal analyses. In combination with static analyses, the force sensitivities were calculated and compared

to a single-beam force sensor with the same resonator dimensions. In particular, the influence of the clamping region on mechanical decoupling of the resonator from the supporting bulk material was analysed.

Mechanical decoupling of a single-beam resonator was proposed by Albert [10]. To minimize energy dissipation coupled into the supporting structure, a mechanical isolation system was employed in the sensor design. Multiple-beam resonators like DETF, triple- or quadruple-beam types include inherent dynamic moment cancellation when they are excited in an anti-symmetric vibration mode. A major task of the numerical modelling was to design an appropriate mechanical decoupling zone for the triple-beam resonator. At the same time, a mode spectrum of the whole sensor device preventing mode interference caused by a force-dependent shift in resonance frequency had to be found [11].

The schematic diagram of the triple-beam sensor device is illustrated in Fig. 1. Moreover, the sensor includes two shunts with wafer thickness for overload protection and a laser-cut mounting hole at each side of the bulk area, allowing uniaxial force loading. The triple-beam resonator is connected to the bulk material on both sides via flexible decoupling zones. The thickness of the decoupling zone is equal to that of the beams, allowing energy transfer during vibration. The length of the decoupling zones was optimized by finite-element (FE) modelling. A micrograph of the sensor device revealing the electrode patterns and bonding pads is shown in Fig. 2.

The dependence of the resonance frequencies for the first three flexure modes on decoupling zone length is shown in Fig. 3. The fundamental flexure mode of the beams vibrating symmetrically in phase is denoted M1. A spurious overtone mode M2 occurs between mode M1 and the antisymmetric sensor mode M3. Using an FE model with 2-D plastic shell elements and assuming isotropic material behaviour, the resonance frequencies and flexure mode shapes were calculated. The analysed triple-beam resonator has a length

of 3 mm, a thickness of $20\text{ }\mu\text{m}$ and beam widths of 400 and $200\text{ }\mu\text{m}$, respectively. The distance between the beams is $50\text{ }\mu\text{m}$. The length of the decoupling zone is $200\text{ }\mu\text{m}$ (i.e., 6.7% of the beam length), causing mechanical decoupling and leading to a sufficient splitting of the vibration modes. This yields an increased unimodal behaviour of the resonant sensor. The resonance frequency of the single-beam resonator is reached for vanishing decoupling length.

The numerically calculated results for single-beam and triple-beam resonant force sensors are summarized in Table 1, comparing the static and dynamic behaviours of both resonator types. The fundamental flexure resonance frequencies and their shift due to mechanical loading (force: 1 N) were calculated. In comparison to the single-beam force sensor, the triple-beam configuration exhibits a larger force sensitivity due to stress concentration, mentioned by Kirman [6]. The stress within the single beam is about 56 MPa and increases to about 63 MPa due to the smaller cross section of the triple-beam resonator. In contrast to single beams, the triple-beam structure exhibits increased force sen-

toresist mask had to be considered in the mask layout. A sputtered and patterned Al metallization layer followed by $\text{SiO}_2/\text{Si}_3\text{N}_4$ passivation layers is used as the top electrode contact for the ZnO transducer film.

After completing the planar front-side process, anisotropic wet KOH etching from the reverse side is applied to produce the desired beam thickness of approximately $20\text{ }\mu\text{m}$. During this etching process the front side of the substrate is protected by an O-ring sealed wafer protection box comparable to the apparatus described by Kung *et al.* [16]. In the following process step the triple-beam resonator structure is separated by plasma-etching the diaphragm from the front side. In order to perform the investigations concerning the influence of the clamping region on the dynamic sensor behaviour, a possibility for flexible redesign had to be considered. This could be achieved by changing only the photolithographic mask defining the plasma-etched areas.

A specially developed laser-cutting process is applied to release the sensor devices and to realize mounting holes in the sensor bulk material (see also Fig. 2). These precisely cut mounting holes provide force measurements with uniaxial application of an external load. The sensor mounting, schematically shown in Fig. 6, is suitable for hysteresis-free force measurements.

Experimental results

Several measurement techniques were utilized for the mechanical and electrical characterization of the ZnO thin films. The mechanical properties of ZnO were estimated with indenter measurements, resulting in a reduced Young's modulus $E/(1-\nu^2)$ of 125–173 GPa for 2–3 μm thin layers. Assuming a value of $\nu=0.36$ for Poisson's ratio, a mean Young's modulus E of about 130 GPa can be deduced.

The electrical characterization was carried out by measuring the impedance/phase characteristics of different resonant structures. The effective electromechanical coupling factors $k_{\text{eff}}^2 = (f_a^2 - f_r^2)/f_a^2$ [17] were determined by measuring the fundamental resonance

frequency f_r and antiresonance frequency f_a of the piezoelectric one-port resonators. Due to the dependence of k_{eff} on resonator geometry, silicon/ZnO thickness ratio, and electrode configuration, measurements were correlated with piezoelectric FE modelling results [18]. The measured k_{eff} values for the triple-beam resonators were about 6–9% for an electrode deposited on 20% of the beam lengths at each side.

A laser vibrometer (POLYTEC OFV1102) was used to measure the mode spectrum of the resonators. Due to the optical readout, all electrodes could be used for excitation, resulting in a high mode selectivity for symmetrical modes. Enhancement of the mode-selective excitation in a real test environment might be achieved by employing a multiple electrode configuration [19]. Optically measured flexure mode spectra (M1, M2, M3) of a force sensor with (a) coupled and (b) decoupled triple-beam resonators are shown in Fig. 7. The clamping of the coupled resonator is defined by the angle of the slow-etching (111) crystal planes of the silicon bulk. In this case there is no decoupling zone and therefore

TABLE 1. Comparison of the numerically calculated static and dynamic characteristics for single-beam and triple-beam force sensors (decoupling length: 200 μm)

Characteristic	Single-beam resonator	Triple-beam resonator		
Mode	fundamental	M1	M2	M3
Frequency (kHz)	19.48	15.51	16.62	17.61
Sensitivity (kHz/N)	14.95	15.43	15.55	15.85
Elongation (μm)	0.98		1.27	
Stress for $F=1\text{ N}$ (MPa)	56		63	

sitivities with higher vibration mode numbers. Furthermore, the force sensitivity of the sensor device is adjustable by adequate selection of the resonator thickness in combination with the widths of the two suspending shunts for overload protection.

Technology

Piezoelectric thin-film ZnO is a promising and widely used material for electromechanical transducers for high-frequency surface acoustic wave (SAW) as well as for low-frequency bulk acoustic wave (BAW) applications [12, 13]. In this work the transverse piezoelectric effect of highly oriented polycrystalline ZnO layers is utilized for exciting the flexural vibration modes (M1, M2, M3) of the triple-beam resonator. Schematic cross-sectional views demonstrating the thin-film multilayer structure and the contacts to the electrodes of the triple-beam force sensor devices are shown in Fig. 4. The fabrication process of these triple-beam resonators can be divided into a front-side and a reverse-side process, comparable to that described by van Mullem *et al.* [14]. Starting with double-faced polished n-type $\langle 100 \rangle$ silicon wafers (4 in), the patterning and p⁺-doping of the ground electrode areas separated from each other on both sides of the triple beam are carried out on the front side of the silicon substrates. In order to achieve an optimum electromechanical coupling, the ZnO, crystallizing in hexagonal wurtzite lattice structure, has to be grown with the c-axis perpendicular to the film plane and the silicon substrate, respectively. For deposition of well-oriented 3 μm thick ZnO films, we used a planar r.f. magnetron sputtering system. In Fig. 5 Bragg reflection analysis measurements of thin sputtered films are shown, revealing a high c-axis orientation of the ZnO. From a Gaussian fit on the peaks enveloping the curve, an orientation distribution with a FWHM of 0.28° was calculated. A pure (99.999%) ZnO target and a mass-spectrometer-monitored Ar/O₂ sputter gas mixture was used. The etching and patterning of the ZnO layer are performed in a stirred solution of HAc, H₃PO₄ and H₂O [15]. The lateral under-etching (several microns) of the pho-

TABLE 2. Comparison of calculated and measured splitting of resonance frequencies for the three flexure modes of a triple-beam resonator

Decoupling length	FE modelling		Experimental data	
	50 μm	200 μm	bulk clamping	200 μm
c_1	1.0	1.0	1.0	1.0
$c_2 - 1$	0.3%	7.2%	0.5%	7.0%
$c_3 - 1$	0.6%	13.5%	0.7%	13.0%

the modal behaviour exhibits a superposition of the three flexure modes (Fig. 7(a)). The mechanically decoupled resonator with a decoupling zone length of 200 μm shows an increased mode splitting of 3 kHz (Fig. 7(b)). This value corresponds to an approximately 30 times higher mode splitting compared to the coupled resonator. The numerically calculated and measured resonance frequencies of the three flexure modes are summarized in Table 2, in which the resonance frequencies were normalized to mode M1 ($c_i = f_i/f_1$). An assumed decoupling length of 50 μm (see Fig. 3) results numerically in a mode splitting within 1%, corresponding to the triple-beam resonator with bulk clamping, whereas a decoupling length of 200 μm leads to a frequency shift of 7% for mode M2 and 13% for mode M3, respectively. The numerical calculations are in satisfactory agreement with the experimental results. Due to the optical readout at the centre beam, the decoupled

resonator reveals a vanishing contribution of the vibration mode M2, which could be optically detected at the outer beams. The mechanical quality factors Q of the vibration modes increase from M1 to M3 by a factor of two. The maximum value of Q was measured to about 400 for mode M3 at ambient pressure conditions. The measured force/frequency characteristic of a triple-beam force sensor is shown in Fig. 8. The high residual stress of the ZnO thin film means that a V-shaped force/frequency characteristic is obtained. The measured force sensitivity is about 8.6 kHz/N for the right branch. For sensor applications the residual stress has to be decreased in order to obtain a single-valued force–frequency dependence.

Conclusions

A triple-beam resonant force sensor with piezoelectric excitation was fabricated. Experimental characterization by means of optical and electrical measurement techniques was performed. The presented resonator configuration is capable of providing a sufficient mechanical isolation from the support by means of a flexible decoupling region and at the same time reveals a better mode selectivity. In combination with vacuum encapsulation, in particular, the triple-beam resonator provides intrinsic advantages in comparison to single-beam resonators. The benefits of the presented resonator

design seem to be promising for future resonant sensor applications.
